Abstract

Molecular modeling study of the structure of model oligomers based on the diglycidyl ether of bisphenol-A with covalently attached dendritic fragments containing azochromophores and dendritic fragments has been carried out. While studying dimers we found conformations with stacking organization of chromophore groups. Features of binding in similar stacking structures were studied within topological approach "Atoms in Molecules", the existence of van-der-Waals interactions between the chromophores was established. For the stacking structure of the chromophore and the individual quantum-chemical TDHF method at the level of HF, as well as with the use of DFT (functionals B3LYP and B97D) there were calculated electric characteristics (dipole moment μ and molecular polarizabilities α, β). It is established that the presence of stacking structures increases the nonlinear-optical activity of molecular system.
