Abstract

In the present study we investigated the effect of treatment of magnesium alloy ML5if of modification mixture of ZrO₂ dispersed particles and cryolite. The object of investigation is magnesium alloy ML5if, which found wide application in shipbuilding. As a result of studies found that magnesium alloy ML5if treated by modification mixture has a reduced grain size of the metal matrix and causes a change in the mechanism of phases formation, whereby observed formation of Zr₃Zn₂ Zr₂Al phases and at the interface of the metal grains. Changing the phase composition and grain size of the metal increases the corrosion resistance of the alloy in an aqueous solution of NaCl.
